Aesthetics and protection

The façade of any building is far more than its aesthetic “face” – it fulfils various functions, all of equal importance to the structure as a whole. Primarily it needs to protect the fabric of the building from the effects of weather – cold, heat and rain. It also plays a key part in sound proofing the building and providing fire protection. Thermal protection is, of course, the most essential performance. FOAMGLAS® ensures that all the demands made on an insulation material are fulfilled with a performance that remains totally effective for the lifetime of the building.
FOAMGLAS®
the ultimate insulation

FOAMGLAS® cellular glass insulation is unrivalled in performance whatever the building system. Cellular glass is foamed glass and constitutes of millions of closed, gas filled glass cells, which provide superior insulation characteristics. Due to the all glass cell geometry, the “vapour-control layer” is already built-in.

FOAMGLAS® is water- and vapour-proof, which means it is totally impervious to any form of moisture. Its high compressive strength makes the insulation resistant to compression – even under permanent loading. Other outstanding physical qualities of the glass material are: non-combustibility, dimensional stability (it cannot shrink or swell), it is rot-, insect-, vermin- and acid-proof (it will not support the growth of mould). FOAMGLAS® is environmentally sound (from manufacture to disposal) and is suited for all types of façade. The thermal insulation value remains as installed, for the lifetime of the building. The importance of the insulation and its performance cannot be overstated and is the key to an effective and financially efficient façade system.

Materials, structures, colours and shapes: Every type of imaginative façade can be combined with FOAMGLAS® insulation. The FOAMGLAS® solution enables architect’s schemes to be realised and adds to the structural stability of the whole cladding concept. Independent of the wall- or cladding-system: Cellular glass insulation ensures exacting insulation values and the avoidance of cold bridging with a particularly thin façade structure. Nearly all façade materials are suited.

- Warm façades: natural stone, clinker brick, metal, glass
- Ventilated façades (curtain wall): stone, timber, metal, glass, acrylic glass, fibre cement, wire mesh, trellis for greenery
- Cavity wall insulation: brick, lime-sand brick, exposed concrete

For all demands: Whatever the weathering and temperature conditions a building may be exposed to, FOAMGLAS® protects the building structure and optimises the energy needs for heating or air-conditioning.

Cost-efficiency: FOAMGLAS®-insulation systems convince the client for their durability. In many a façade rehabilitation the existent FOAMGLAS® insulation was found unchanged after 40 years of use and could be left in place.

Safety: FOAMGLAS® proves to be the “safety insulation”. This also means “fire safety”. Cellular glass insulation is classified as non-combustible to Euro Class A1 – no contribution to fire.

Ecology: FOAMGLAS® is ecologically sound and has no environmental health hazards. Due to its outstanding service life and overall environmental sustainability, FOAMGLAS® cellular glass is best-rated in comparative analysis of environmental product declaration.
Intercontinental & Crown Plaza Hotel, Festival City, Dubai

**Client** Al-Futtaim Group  
**Architect** Cox Crone Architects  
**Construction** 2003 – 2007  
**Application** of FOAMGLAS® behind stone cladding facade 8000 m²

The Intercontinental and Crown Plaza Hotel are part of Festival City project which will be once finished one of the largest mixed-used development in Dubai. FOAMGLAS® is used behind the stone cladding because of the unique property of fully resistant to any kind of water and vapour and therefore can be applied on the wall structure without any additional protection against the high humidity. No additional foil for vapour protection is required through the closed cell structure of the material FOAMGLAS® itself. Result is the lifetime constant performance of the thermal insulation. Degradation through humidity abortion is the biggest problem in the Middle East for wall insulation next to fire issues. FOAMGLAS® is fully inorganic and will not support any fire. With no flame spread and no smoke development it provides specially in hotel project with towers the highest safety and ensures even in the building envelope the highest standard.

Long term investment in safety and durability

3. FOAMGLAS® mechanically fixed  
4. Structural wall concrete
Apartment house Steinhofstrasse, Lucerne

**Architect** Rüssli Architekten AG, Lucerne  
**Construction** 2002  
**FOAMGLAS® application** Façade insulation, about 175 m², T4+ slabs, 120 mm thick, adhesively bonded  
**Façade cladding** Folded metal cladding, warm façade (without ventilation space), fasteners/cleats are fixed to PC fixing plates (or claw plates)

As FOAMGLAS® is vapour-tight folded metal cladding can be installed without the need for a ventilation space. The number of elements needed is minimised, expensive and complicated sub-constructions such as additional lathing, roof boarding as a bearing course for the standing seam and ventilation slots are not needed. This saves costs and the construction thickness is reduced to a minimum. Simplicity and gain on the interior volume make the FOAMGLAS® solution a most economic system.

**Simplicity and economy due to reduced number of elements and gain of space**

www.foamglas.com

**Façade structure**

1. Concrete load bearing structure  
2. FOAMGLAS® T4+ insulation, adhesively bonded  
3. PC fixing plates (claw plates) fixed to the structure and cleats for fixing the folded metal cladding  
4. Folded metal cladding (standing seam sheets)
‘Schweizerhaus’ building, Romanshorn

Architect D. Bötschi, Architekt ETH/SIA, Egnach
Construction 2003
FOAMGLAS® application Façade insulation, about 450 m², T4+ slabs, 120 mm thick, adhesively bonded with surface coating applied to the insulation
Façade cladding Concrete slabs with sandstone finish, 50 mm thick, dimensions 800 x 600 and 800 x 200 mm, mechanically fixed with single structural fasteners

When façade claddings are inclined inwards they impose high demands on the thermal insulation applied to the structure. Water infiltration will occur and only the use of additional sealing methods or thermal insulation which is water-tight and totally resistant to moisture will protect the structure from becoming wet. FOAMGLAS® slab insulation – together with its surface coating – will prevent water inflow through the joints from reaching the structure. No membrane is required. Protection against heat loss and the effects of moisture is ensured in the long-term.

Cladding Natural stone cladding

The Bachhaus Eisenach is the first museum in the world dedicated to Johann Sebastian Bach. It contains not only archive materials, household effects and bibliographic treasures from the times of Bach, but also a valuable collection of musical instruments as well as a specialty library.

To ensure lifetime performance of the façade it is not only the outer skin that needs to be high-end, but also the support structures and the thermal insulation layer in order to meet the quality demands. The FOAMGLAS® system provides high functional performance and is unaffected by driving rain and water vapour. It meets all the requirements of this type of high quality façade system and will perform for the lifetime of the building.

When façade claddings are inclined inwards, they impose high demands on the thermal insulation applied to the structure. FOAMGLAS® gives full security, as it does not sag or warp and cannot create any blockage of the rear ventilation space. FOAMGLAS® provides heat and moisture protection in any position. The design possibilities are limitless.

**Construction** 2007  
**FOAMGLAS® application** behind stone cladding facade mechanically fixed.  
Total area of FOAMGLAS® applied for facade and flat roof 22 000 m²

The Museum of Islamic Art is situated on the southern part of Doha’s seafront on a manmade island about 60 meters off the coast of Doha. The external wall of the Museum is finished with 6,500 M³ of natural stone work. High temperature combined with high humidity and an open joint application of the facade was asking for a high quality of the structure below, specially the thermal protection because access to the ventilation space is not provided any more. The FOAMGLAS® cellular glass insulation with the closed cell structure guarantees a life term solution because it can never absorb any humidity neither from humid air nor from rain or condensation. The lifelong constant performance is ensured and any upgrading of HVC equipment never required.

**Construction** 2003  
**FOAMGLAS® application** Exterior insulation, Type READY BLOCK, thickness 100 mm, adhered  
**Cladding** Stainless steel shingles, battens and counter battens fixed to substrate

Beiersdorf AG has its research and development centre in Hamburg-Eimsbüttel. They centralise the core activities of cosmetic research and development in different sections, laboratories and office buildings. An auditorium with a capacity for 500 people has been added as an extension. With its contrasting organic shape it forms a visual contrast in the green courtyard, surrounded by geometric buildings.

A range of materials such as brick, glass, metal and fair-faced concrete is used for the "skin" of the old and new buildings, linked by a bridge. FOAMGLAS® is non-combustible and unaffected by water or water vapour. FOAMGLAS® eliminates the potential of any damage to the wall system or insulation itself from rodents, insects, birds, etc. as it provides no source of food for nesting animals.

Constructor  Nexometal
Thermal insulation  7000 m² FOAMGLAS® READY BLOCK 60 mm
Finish  Composite Panel

Having extended and renovated its existing building, the IAACC (Instituto Aragonés de Arte y Cultura Contemporáneos) Pablo Serrano re-opens its doors and is set to become a benchmark for contemporary culture not just in the Aragon region but on a national and international level. The newly opened museum aims to provide deepening knowledge of the Aragonese sculptor from whom it gets its name. The Pablo Serrano Museum is located in the old workshops of the Provincial Orphanage, which were refurbished by the architect José Manuel Pérez Latorre, to suit the new role as museum. The interior includes the work of Pablo Serrano combined with temporary exhibitions of contemporary painting and sculpture. The space of the new building is amazing, with its volume increased from 2,500 m² to 7,500 m², it is furthermore enhanced by an unusual fenced area incorporating an external light enclosure which is painted in a special colour that looks like "a precious stone reflecting the sky". FOAMGLAS® has been chosen because it could ensure dimensional stability and unaltered performance throughout the entire service life of the building.

FOAMGLAS® application Façade insulation, about 450 m², T4+ slabs, 100 mm thick, adhesively bonded
Façade cladding Timber and aluminium slats, substructure timber or aluminium, visible fasteners for fixing the slats to the substructure

Timber and aluminium slats are often used to create the appearance and effect of cladding; they have open joints and are carried on a substructure of timber or aluminium, allowing ingress of moisture. The use of FOAMGLAS® insulation allows for large spacing between the slats and ensures that rainwater inflow through the open joints of the cladding will not affect the insulation performance and lead to its deterioration. The insulation is finished with a surface filler. The wall construction will remain dry ensuring that insulation values are maintained. Technical and aesthetic design requirements are met.

**Construction** 2003  
**FOAMGLAS® application** Façade insulation, about 600 m², T4+ slabs, 160 mm thick, adhesively bonded, and paint finish  
**Façade cladding** ESG glass cladding, 10 mm thick, with silk-screen printing – discharge print imitation, metal substructure fixed to a structurally fixed supporting plate, glass cladding with visible fixing points

Glass façades impose extreme loads on the substructure and in particular on the thermal insulation behind it. Due to retained heat, extremely high temperatures are created and these can rapidly drop when rain occurs. As a consequence condensation can form in the façade structure. FOAMGLAS® insulation is impervious to water and water vapour and will not allow deterioration from condensation. It has dimensional stability and resistance to expansion or swelling even under severe temperature fluctuations and moisture conditions.

Architect Peter Cook + Colin Fournier, London

Construction 2002/2003

FOAMGLAS® application Roof and façade insulation, special shaped roof, about 3670 m², T4+ slabs, 160 mm thick, adhesively bonded, mechanically fixed in parts

Façade cladding Tinted and open-jointed acrylic panels, visible fixing points on the cladding elements

This special shaped building is a most demanding construction with a complex structure. On this imaginative structure, the external panels are of aesthetic value only; the open joints provide no protection against driving rain or environmental conditions. The layers beneath the panels must fulfil the function of both weather-tightness and insulation of the building. FOAMGLAS® applied below the membrane effectively meets both these demands and the clamping system ensures the minimum of cold bridging in the wall and roof constructions. Independent of the type and shape of load-bearing structure – concrete or steel deck, flat or curved – cellular glass insulation is easily cut to shape and will perfectly adhere, with a maximum of contact surface, to the structural wall/roof. Proud edges on the insulation can easily be smoothed with a grinding tool. With FOAMGLAS® insulation all design options are possible.

Texas A&M University Doha-Qatar

**Architect** Halcrow  
**Construction** 2005 – 2007  
**Application of FOAMGLAS®** in cavity wall

Texas A&M at Qatar is part of Education City, home to branch campuses of some of America’s best universities and academic programs. The university offers undergraduate degrees in chemical, electrical, mechanical, and petroleum engineering. A two layer brick wall does not provide a fully water and vapour proof external shell and high humidity and extreme heat can affect the thermal insulation between. With the use of FOAMGLAS® a material is used which will never warp, sack or lose any of the performance over the whole lifecycle of the building. FOAMGLAS® will remain dry and provides constant performance, is fully inorganic and will not support any fire. No flame spread and no smoke development.

Risk reduction for non-accessible structural components

Construction 2003
FOAMGLAS® application Cavity wall insulation, about 2140 m², T4+ slabs, 40/200 mm thick, adhesively bonded
Outer shell Cast-in-place concrete (exposed concrete)

Twin-skin concrete constructions make high demands on the insulation material. The insulation layer is unapproachable later and has to be particularly robust to face a number of risks which include: the effects of high loading and moisture when the concreting for the outer shell is done as well as possible water infiltration through cracks and damaged joints during and after construction. It is with good reason that FOAMGLAS® is called “safety insulation”. Due to high compressive strength and imperviousness to moisture, it ensures that all the demands made on the insulation material are fulfilled with a performance that remains totally effective for the lifetime of the building.

Considerations regarding the quality and durability of buildings

Traditional fields of building physics are thermal insulation, protection against moisture, sound proofing and fire safety. The elimination of undesirable physical interactions is most important for the quality of the building and healthy living conditions. Determinants are – in addition to economic issues – system performance, service life, indoor climate, energy efficiency and environmental impact. The target of building physics is to improve the living conditions for the occupants and to protect the building against undesirable effects. At that thermal insulation plays a key part.

Particularly with regard to the growing interest in low-energy houses, thermal insulation and energy-saving technology is of primary importance. Thicker insulation on all enclosure surfaces is certainly an important step to be taken, however the wall structure has to be designed and fitted accordingly, in particular at door and window openings.

Inadequate thermal insulation should not be underestimated, as it may not only cause heat loss but constitute a serious risk for the building’s structure itself. Well designed thermal insulation significantly saves energy costs and provides protection against damage on the building.

Avoidance of cold bridging

Ventilated rainscreen cladding systems appear to be a safe solution in view of building physics. With the right choice of materials and design, the rainscreen cladding can efficiently provide protection from the effects of weather in the
long term and enable the most imagi-
native scheme to be realised. As a rule, 
cold bridging should be avoided. These 
weak points are created where 
mechanical fasteners for the suspen-
sion of the rainscreen cladding have 
through-fix anchoring which generate 
additional energy loss.

A number of studies – for example by 
EMPA Dübendorf (Swiss Material Testing 
Institute) – have been made to evalu-
ate the heat loss that occurs in many 
wall constructions because of the 
structural support element for the 
cladding passes through the thermal 
insulation and onto the load bearing 
structure. Measurements from field 
studies for different façade systems 
were compared to computational 
results from a three-dimensional pro-
gram. As a result: The support and fix-
ing method has a considerable influ-
ence on the overall insulation value of 
the rear ventilated façade. A high level 
of heat loss has been seen, about 
13–80% dependent on the type of 
construction and the materials (see 
figures “Heat losses” on pages 26/27). 
This undesirable effect is maximized 
with growing insulation thickness – which obviously correlates with heav-
ier structural fasteners.

For energy policy reasons, the trend 
towards thicker façade insulation is
increasing not only in Switzerland, but 
Europe wide. It is absolute necessity to 
develop new, innovative and energy-
efficient solutions. The Swiss ‘Bundes-
amt für Energie’ (BFE, Federal Office 
for Energy) and ‘Fachhochschule 
Nordwestschweiz/beider Basel’ 
(FHNW/ FHBB, University of Applied 
Sciences Northwestern Switzerland) 
took the initiative and invited the 
industry to an idea contest. In the 
beginning of 2000 ten teams were 
selected to develop the subject 
“Thermally optimised structural sup-
port elements for ventilated rainscreen 
cladding systems”. The FOAMGLAS®-
team obtained the first price with 
enterprise allowance for the new 
cladding support system FOAMGLAS®-
plus.

The FOAMGLAS®-plus system

This new concept for rainscreen 
cladding support reduces cold bridg-
ing and achieves best overall insu-
lation values for ventilated façades. By 
use of high compressive strength 
FOAMGLAS® insulation adhesively 
bonded to the structural wall and 
placement of the metal fixing 
plate/claw plate – or T-console for 
heavier façade systems – to support 
the subconstruction/cladding in front 
of the insulation, a system is available 
that minimises cold bridging.
The new façade system FOAMGLAS®-
plus works with the following compo-
nents:

- The self-supporting insulation in 
high-compressive strength FOAMGLAS® 
is adhesively bonded to the load bear-
ing wall and forms a totally integrated 
surface, without effects of heat losses 
and air leaks. (Joints are closed and 
water-tight, additional support for the 
insulation is provided at window/door 
lintels and at the base of the wall by 
use of angle bars).
- Metal fixing plates (U-shaped claw 
plates in galvanized steel) are pressed 
on to the FOAMGLAS® surface, adhe-
sively bonded and mechanically fixed 
to the structure. The fixing level for the 
ventilated rainscreen cladding is placed 
on the upper side of the insulation, an 
installation method, which creates 
minimal cold bridging.
- Metal fixing plates (claw plates) and 
bolt/screw connection to the main 
structure allow for a safe mounting of 
conventional façade support structures 
(in timber, metal) to bear the cladding 
elements. The system is designed for 
lightweight to medium-heavy cladding 
elements of small, medium or large 
size.

Adhesively bonded facing elements/bricks on FOAMGLAS® insulation

By the thermally optimised mechanical fixing of the support structure for rainscreen cladding – due to the FOAMGLAS®-plus system – remarkable improvements on the overall insulation value of the ventilated façade can be achieved.

Absolutely best performance without heat losses – for a minimized thickness of the façade structure – can be achieved without any through fixings. A façade structure excluding all cold bridges is possible when the outer leaf is directly bonded to the insulation. FOAMGLAS® insulation is the robust and versatile material that has the required properties for this type of building solution.

Air tightness of insulation and system

Air tightness of the system is achieved by the closed cellular glass structure of FOAMGLAS® and the adhesively bonded insulation layer itself with sealed joints. The installation method minimizes any risks from interstitial condensation. Heat losses due to the effects of air flow on insulants with low resistance to the passage of air, will not take place with the FOAMGLAS® system.

Use of FOAMGLAS® insulation allows for a totally integrated surface without the need to cut lengths around anchors and to stuff openings against air leaks.

FOAMGLAS® has best dimensional stability. It will not warp or sag and cannot create any blockage of the rear ventilation space. It remains stable under all conditions of use and temperature fluctuations and moisture will have no adverse effects. Butt-pressed and adhesive sealed joints ensure the structural stability of the system in the long-term; there will be no danger of air leaks and additional heat losses to develop in the course of time.

---

1. **Waterproof** FOAMGLAS® is waterproof because it consists of pure glass. **Advantage:** does not absorb any moisture and does not swell.

2. **Pest-proof** FOAMGLAS® cannot rot and is pest-proof because it is inorganic. **Advantage:** insulation without risk, especially in the base area and the soil. No basis for nesting, breeding or seed germination.

3. **Compression-proof** FOAMGLAS® is extraordinarily incompressible even with long-term loads due to its cell geometry without deformation. **Advantage:** use as load-bearing thermal insulation without risk.

4. **Incombustible** FOAMGLAS® cannot burn because it consists of pure glass. Fire behaviour: Classification according to EN 13501: A1. **Advantage:** storage and processing not hazardous. No propagation of flames in the event of fire (chimney effect) in ventilation space.

5. **Vapour-tight** FOAMGLAS® is vapour-tight because it consists of hermetically sealed glass cells. **Advantage:** cannot soak through and already contains the vapour barrier. Constant thermal insulation value over decades. Prevents the penetration of radon.

6. **Dimensionally stable** FOAMGLAS® is dimensionally stable because glass neither shrinks nor swells. **Advantage:** no dishing, contracting or creep. Low coefficient of expansion, nearly equal to that of steel and concrete.

7. **Acid-resistant** FOAMGLAS® is resistant to organic solvents and acids because it consists of pure glass. **Advantage:** no destruction of the insulation by aggressive mediums and atmospheres.

8. **Easy to work with** FOAMGLAS® is easy to work with because it consists of thin-walled glass cells. **Advantage:** with simple tools like a saw blade or hand saw, FOAMGLAS® can be cut to any desired measurement.

9. **Ecological** FOAMGLAS® is free of environmentally damaging flame retardants and propellants, no relevant eco-toxic components. **Advantage:** After generations of use as thermal insulation, FOAMGLAS® can be used again: as filler in landscaping or thermally insulating granulate. Ecologically sensible recycling through re-use.
Bad workmanship and unsuitability of materials can have a dramatic effect on the thermal insulation values, particularly with cladding systems. In how far faulty workmanship on insulation has influence on the percentage of heat loss caused by cold bridging, has been shown by EMPA studies on ventilated façades (see pictures below). Additional heat loss caused by cold bridging can vary considerably in function of the quality level of workmanship. In case of air circulation around the insulation board, the heat loss from thermal transmittance can bump up to a considerable degree.

1. Anchoring system: Suspension and fixing systems
   a. Load bearing wall
   b. Thermal insulation
   c. Single structural fastener

   The quality of the workmanship on site can influence the heat losses by up to 30% (due to air leaks through the notches around fasteners in fibre wool insulation)

2. Ideally the structural fastener is perfectly encased
   +34%

3. In practice the encasement of structural fasteners is less perfect
   +50%

FOAMGLAS® ensures that all physical and thermal demands are fulfilled

- FOAMGLAS® provides groundbreaking system solutions that significantly reduce the likelihood of cold bridging.
- The FOAMGLAS®-team draw first prize for the new façade insulation system FOAMGLAS®-plus, following a call for proposal by Swiss Federal Agency for Energy.
- FOAMGLAS®-plus: By use of metal fixing plates/claw plates applied to the insulation surface, the fixing devices for the subconstruction and cladding elements are positioned in front of the insulation layer, thus greatly reducing cold bridging.
- Another construction variant allows facing elements/bricks to be directly bonded to the FOAMGLAS® surface. This solution provides a totally cold bridge-free façade structure. FOAMGLAS® has the product qualities to fulfil the specific requirements of this system.
- FOAMGLAS® cellular glass insulation is totally air tight and the adhesively bonded slabs with closed joints ensure as well for structural integrity and optimal air tightness of the system.
- High density and dimensional stability of FOAMGLAS® add to the structural stability of the whole cladding concept and ensure that the insulation will not warp or sag when the building work is complete.
Fire protection

After fire disasters heated discussions are aroused regarding responsibilities and fire precautions. Closer examination puts the question if the fire and the development of dangerous fumes could or should not have been prevented? The part played by insulation materials is a frequent issue. Studies provide clear evidence: FOAMGLAS® contributes to efficient passive fire protection. Cellular glass is non-combustible and does not give off fumes or toxic gases.

Preventive action starts with the choice of materials

“Fire disaster ... fire safety provisions violated ... two victims are still fighting for their lives ... there is evidence that fire safety regulations have been ignored ... rapid propagation of the fire has been encouraged ... sea of flames.”

These headlines make evident: To extinguish a fire in a building is sometimes rather difficult – even if building regulations on fire safety have been observed – because of the scale of the fire and the degrees of heat. The unfortunate coincidence of different factors can be the cause, as for instance a high fire load on the inside of the building, rapid spread of fire effluents, high wind and difficult access to the seat of fire. Reports of fire and rescue services can speak volumes ...

All the more care and attention has to be given to passive fire protection. By choosing adequate construction materials the risks of fire development – in particular the spread of fire across voids and flammable materials – can be reduced significantly.

Smouldering fires – extraneous perils

Fires of this nature generally spread inside construction elements where they may go undetected for a long time. Sometimes hours may pass by between ignition and detection of the fire.

The specific structural and chemical characteristics of some insulants increase the risk of smouldering fires. This is not the case with FOAMGLAS®. The all glass closed cell structure of the insulation forms a shield.
**FOAMGLAS®**: Neither fumes nor toxic gases

Fire disasters must not always be identical with “a sea of flames”. Have a flashback to the events on Düsseldorf Airport (1996) with 17 casualties and the fire in the Montblanc Highway Tunnel (1999), which caused the death of 39 people. In both cases toxic effluents from insulants, that were not fire safe, were considered responsible for the fatality (polystyrene in Düsseldorf, polyurethane at the Montblanc rock).

By contrast FOAMGLAS® does not give off fumes or toxic effluents. In respect of fire safety FOAMGLAS® is classified A1, non-combustible. The material with its all glass closed cell structure does not contain any binders.

Regarding fire safety FOAMGLAS® performs unlike all other insulants, classified as “non-combustible”. The big difference is that FOAMGLAS® does not glow or smoulder and does not cause the spread of fire across the construction.

**FOAMGLAS® melting point > 1000 °C**

According to German DIN 4102-17 the melting point of FOAMGLAS® was tested at MPA Braunschweig Institute (D). More than 50% of the insulation thickness lasted the 90 minute fire period without significant damage. As an official result the melting point is >1000 °C.

**General protection with FOAMGLAS® in case of fire: Melt Shield-Effect**

Comparable as a thermal protection shield the melted glass surface of the flame treated area is protecting the lower cell structure. The temperature on bearing structure is remaining low. FOAMGLAS® is defending the building structure in case of fire.

**To play safe: FOAMGLAS® for insulation**

Recent fire testing yielded that cellular glass has excellent fire control attributes. Relevant test certificates are available from the national FOAMGLAS® subsidiaries. With regard to recent findings in preventive fire protection, architects and clients should redefine their safety requirements, which should be geared towards low-risk management for the façade structure under fire conditions.

If it is about quality standards in building, it makes sense to consider as well appropriate fire safety measures. Fire inquests are supposed to demonstrate the need to builders that the demands on fire safety should clearly be defined at an early stage in cross-functional cooperation of planning offices/architects, contractors and the client himself.

---

1 Fire in an apartment house, Lucerne, Switzerland.
2 Fire and toxic effluents: On Düsseldorf Airport a fire caused 17 casualties.
3 Conclusion after test procedure: FOAMGLAS® melting point > 1000 °C.
**FOAMGLAS® provides superior performance regarding preventive fire protection**

- FOAMGLAS® is a safer product as it is pure and non-combustible cellular glass insulation. Reaction to fire classification: EN standard, Euro Class A1, Technical Agreement by VFK Nr. 5273).
- FOAMGLAS® thermal insulation performance is unaltered when exposed to extreme temperatures. The material does not soften up to 430°C and does not sag.
- Closed cell FOAMGLAS® insulation prevents oxygen to pass through the material to tease the trouble spot.
- FOAMGLAS® is gas-tight. The passage of hot gases through the insulation and their development inside the insulant is to be excluded. FOAMGLAS® is a safety insulation that forms a barrier against the propagation of the fire.
- Vapour-proof FOAMGLAS® does not need any additional protective layer, type vapour control layer. This means that the fire load is insignificant when compared with other insulants.
- FOAMGLAS® does not develop any flammable combustion residues, fumes or toxic effluents which can be harmful to health.

1 The figure shows the existing temperatures on a façade for three fire test set-ups under large-scale fire conditions.
**Durability is the key to economy**

Successful property developers and house-builders plan ahead while taking investment decisions. Not the first low-priced solution that comes along is given the preference, but cost-efficiency in the long-term which yields a good return of investment pays out to be most profitable. This means that the protection of the fabric of the building, quality materials for the enclosure walls and a greater versatility in use for the interior surfaces are the main demands. With regard to energy efficiency the insulation material should provide a performance that remains totally effective for the lifetime of the building. FOAMGLAS® is able to fulfil these demands and moreover achieves the best useable floor ratio. The design structure of the insulated walls can be slimmer than for other insulation materials, which creates more useable space within the building structure.

**Secret qualities**

Be it residential, commercial, industrial or public constructions: the quality of the insulation system for the roof and the façade is decisive for the service life of the building’s structure. As with the flat roof it can be shown for the façade that long-term efficient constructions are more economical than cheap solutions. The façade of a building fulfills an important function: it needs to protect the fabric of the building from the effects of weather – cold, heat and rain. A wide range of aesthetic cladding materials in a great number of colours and shapes, including concrete, bricks, ceramics, natural stone, metal, fibre cement and many others, can be used. Usually they can protect a building for a period between 10 to 50 years or even longer. Often it is not the cladding that is the weakest link in the chain, but the thermal insulation.

Due to the effects from moisture, temperature fluctuations, wind and environmental pollution, the service life of many an insulant is shorter than that of the cladding material. Loss of structural integrity – warping and sagging – of the insulation material, which is exposed to climatic changes, will affect its performance and compromise the structural stability of the whole cladding concept.

This is not the case with FOAMGLAS®. The all glass closed cell structure of the insulation remains stable under all conditions of use. With high compressive strength it is robust against all sorts of stresses. FOAMGLAS® remains totally effective for the lifetime of the building.
Unaffected, constant thermal insulation value over decades

Moisture absorption, loss of structural integrity and the passage of air on façades are nightmare scenarios. Quality loss on badly affected insulation material results in considerable heat losses. Extensive repair works will become necessary. In particular with regard to today’s greater insulation thicknesses, heat losses will be a major cost factor.

Due to the specific FOAMGLAS® properties – i.e. the impermeability to moisture, the structural stability – and the bonded installation method which protects against air leaks, a totally integrated surface is created which ensures efficient protection against serious damage.

To conclude: FOAMGLAS® insulation function and value will remain constant for decades; its sustainable performance plays a key part when high standards are required.

No ventilation space – gain in useable space within the building structure

As FOAMGLAS® is impervious to moisture, no rain will wet the insulation on the weather side and no vapour transport will affect it from the room side. This means significant advantages. In summer there is no need for a ventilation space to allow interstitial condensation to “escape”.

Use of FOAMGLAS⁺⁺-plus façade substructures dispenses with the need for a ventilation space and greatly reduces heat loss from cold bridging. The FOAMGLAS® rainscreen cladding system allows to gain several centimetres on the façade structure. This gain in useable space, calculated for the number of floor levels in the building, totals in a substantial gain in space.

FOAMGLAS® – a new dimension in performance + economy

- Building with FOAMGLAS® is preferring a durable and cost-efficient solution instead of a low-end solution.
- FOAMGLAS® offers high structural stability (dimensionally stable) and is resistant to damage from demanding environmental conditions.
- Energy-efficiency in building requires an insulation material where insulation function and value will remain constant for the service life of the building. There is but one: FOAMGLAS®.
- Due to its outstanding physical qualities FOAMGLAS® perfectly resists to moisture, temperature fluctuations, passage of air, environmental pollution etc. and therefore obviates building refurbishment.
- FOAMGLAS® allows for exacting insulation values over decades, a most important item for buildings according to high energy standards like Swiss ‘Minergie-’ and ‘Minergie-P-Standard’.
- The FOAMGLAS® system dispenses with the need for rear ventilation with rainscreen cladding – this gives the advantage of more useable space within the building structure.
Excellent Ecological profile

FOAMGLAS® insulation systems are stable under all conditions of use and protects the owner from unexpected expenditures for heating or expensive replacement of the insulation or repair. FOAMGLAS® systems safeguard the environment one way or another. They allow for energy saving and, from the cradle to the grave, they do not contribute to environmental pollution, a safe product consistent with the principles of building physics. Cellular glass is certified to standards of health and indoor air quality. Ecologically viable product recycling is possible in the case of building demolition.

Production and composition

FOAMGLAS® manufacturing is two sub-processes. In the first part of the process the recycled glass is melted and subsequently batched with the remaining raw materials and crushed in a mill. In the second sub-process the powder mix passes in the cellulating furnace at high temperature where FOAMGLAS® cellular glass is foamed – comparable to the process of fermentation in bread baking.

Typically 60 %+ of the raw material is recycled glass. A very low percentage of carbon is added during manufacturing which makes the charcoal grey color of the insulation. In the cellulating furnace the soft, viscous glass is foamed through release of carbon dioxide (CO₂) and forms millions of airtight glass cells enclosing the gas. This closed cell glass structure ensures full resistance to the transmission of vapor (resistance to water vapor transmission \( \mu = \infty \)).
Environmentally friendly production

The raw materials used in the FOAMGLAS® production are inherently mineral and thus environmentally friendly. Principal raw material is recycled glass. Further raw materials are feldspar, sodium carbonate, iron oxide, manganese oxide, carbon, sodium sulfate and sodium nitrate. By the introduction of recycled glass into the production FOAMGLAS® makes a relevant contribution to the protection of the environment.

Minimal environmental pollution

Due to improvements in process engineering and in the energy supply (coming from hydroelectric energy and wind turbines) significant progresses have been achieved in recent years regarding air pollution, greenhouse gas emissions, consumption of energy and resources:

- The demand for non-renewable energy was reduced 4.24 kWh/kg.
- Greenhouse gas emissions have been halved.
- The percentage of recycled glass was progressively increased from 0 % to 30% and to 60 %.
- The environmental pollution score (UBP97) was reduced from 1619 to 743 points.
- The eco-indicator (EI99 H, A) dropped from 0.13 to 0.09 points.

Reduction of the production energy means that the time period for energy amortization of the investment in thermal insulation – as an important evaluation unit – is considerably reduced.

FOAMGLAS® manufacturing
(Tessenderlo Plant, Belgium)

1 Mixing and batching of the raw materials: Recycled glass, feldspar, sodium carbonate, iron oxide, manganese oxide, sodium sulphate, sodium nitrate.
2 The melting furnace has a constant temperature of 1250 °C.
3 Molten glass is drawn out of the furnace.
4 Control room for monitoring the production.
5 The glass is drawn off and falls onto the conveyor band where it cools down before entering into the ball mill.
6 Addition of “carbon black”.
7 Ball mill grounds all ingredients into a fine powder before putting into stainless steel moulds.
8 The filled moulds pass through a cellulating oven (foaming furnace) with a temperature of 850 °C. This is where the material gains its unique cell structure.
9 Energy recovery of heat.
10 The FOAMGLAS® blocks pass through an annealing oven to allow carefully controlled cooling of them without thermal stress.
11 The blocks are cut to size and sorted by batch. Production waste is recycled.
12 FOAMGLAS® slabs are then packaged, labelled and palletized.
13 Finished FOAMGLAS® products are stored and prepared for transport.
**FOAMGLAS® stands comparison**

The environmental pollution score (UBP 2006**) for the production and waste disposal of FOAMGLAS® is 903 points/kg (insulation). This puts FOAMGLAS® into the pole position in eco-balance. Other insulation products show points between 2020 (stone wool) and 8490 (Extruded polystyrene).

* The data are taken from building database K8OB/EMPA, june 2009.
** The environmental pollution score (UBP 2006) quantifies the pollution coming from resources, water consumption, emissions into air, water and ground and also for the waste disposal. The environment pollution through grey energy and global warming are included in the UBP score.
World resources

The principal raw material of FOAMGLAS® production today is selected recycled glass (in the past the main raw material was silica sand). The supplies of recycled glass are ample, as in the construction and other industries large quantities amass and have to be disposed of as waste. Plastic foam insulation, however, is produced from crude oil, which is a non-renewable fossil fuel.

FOAMGLAS® cellular glass insulation products now with natureplus label

Natureplus, an international organisation for the development of a culture of sustainability within the building sector, has selected cellular glass thermal insulation from Pittsburgh Corning Europe SA as a green building product and awarded the natureplus quality label. “Cellular glass thermal insulation by Pittsburgh Corning Europe SA ideally meets the quality requirements for a sustainable construction product”, noted Uwe Welteke-Fabricius, president of natureplus e.V., when handing-in the certificate. The natureplus quality seal is the symbol of recognition for building products with a high level of quality in the areas of health, the environment and functionality. Pittsburgh Corning’s FOAMGLAS® types W+F, T4+, S3 and F from the Tessenderlo plant (Belgium) are tested and certified successfully.

Service life

Having outstanding qualities (mineral, impermeable to water and vapor, resistant to acids, non-combustible, high-temperature resistant), cellular glass is a very durable material. The long service life of the material has very positive effects, ecologically and financially, on the service-life of the construction and, consequently, on the life of the building. Maintenance and replacement cycles can significantly be reduced by the use of durable materials.

Emissions / nuisance during installation and use

Cellular glass does not release harmful or toxic components into the environment. It does not contain green house gases or ozone depleting products, no flame retardant and no con-taminative or carcinogenic particles and fibers. When recommended installation instructions are followed, cellular glass insulation does not produce emissions that degrade the environment or health, at production, installation nor use.

Emissions in case of fire

Dumping and burning of construction waste is most critical for the environment, even in small quantities. In particular plastic foam materials are classified as harmful. In the case of burning of these materials high levels dangerous emissions are released than in combustion in an incineration plant. Studies have been conducted in Germany on thermal combustion of polystyrene insulation, which clearly indicated that released fumes are acutely toxic. Serious adverse health effects in the long-term cannot be excluded. Even with combustion in a waste incineration plant, there is high impact to the environment, as annually several thousand tons of slag and filter residue have to be transported to special disposal sites. The non-combustibility of cellular glass makes the toxicity issues irrelevant.

Positive ecological assessment for FOAMGLAS®. Source: Cellular glass insulation, a cost-effective and environmentally sustainable solution. [Schaumglas-Dammstoff, Wirtschaftlich und umweltvertraglich Dammren.] Markus Welter, Lucerne
**Waste disposal**

In the assessment of insulation materials one consideration is repercussions on the environment from waste disposal. There are significant differences between the various insulation products. In total evaluation – and considering the scarcity of raw materials – as documented in eco-balance data sheets for the building industry, plastic foam insulation receives poor ratings for environmental pollution.

**Recycling**

Cellular glass being non-combustible, combustion in a waste incineration plant is not a possibility. An option is the recycling of cellular glass as crushed stone (for bedding in road construction) or infill material for noise barriers. Recycled FOAMGLAS® is a safe and suitable product for these applications, as it is dimensionally stable, neutral for the environment, inorganic, rot-proof and without any risks for the ground water (meets ELUAT-test requirements). If crushed and recycled FOAMGLAS® is not used as bedding or infill material, it can be taken to an inert waste disposal site, like crushed concrete or brick.

**FOAMGLAS® – a valuable contribution to the protection of the environment.**

- Today FOAMGLAS® is made from 60 %+ recycled glass. The FOAMGLAS® manufacturing concept is waste reduction and green energy utilisation.
- For the FOAMGLAS® production only energy from renewable sources is used.
- Environmental pollution during manufacturing has halved when compared to 1995.
- FOAMGLAS® insulation meets all environmental and health requirements for construction products.
- At the end of its service-life FOAMGLAS® disposal is simple. One option is the use of recycled cellular glass as infill in trenches or back-up for buried pipes.
- FOAMGLAS® has an outstanding service-life, which is clearly the best for the environment.
- On balance: FOAMGLAS® is an insulation concept fit for the future that gives an answer to the genuine concerns for the environment. The system ensures that all demands on performance, durability, environmental integrity and sustainability are fulfilled.
ELUAT – elution test. FOAMGLAS® meets the requirements of ELUAT test (Investigative report EMPA Nr. 123544 A, based on the successful testing of bitumen coated FOAMGLAS® specimens). According to declaration scheme D.093.09 of the Swiss Technical Directive for Waste Management (Technischen Verordnung über das Abfallwesen (TVA)), FOAMGLAS® is an authorised material for inert waste disposal sites.
